Table of Contents

1 Introduction

yHaplo identifies the Y-chromosome haplogroup of each male in a sample of one to millions. It does not rely on any particular genotyping modality or platform. Although full sequences yield the most granular haplogroup classifications, genotyping arrays can yield reliable calls, provided a reasonable number of phylogenetically informative variants has been assayed.

Briefly, haplogroup calling involves two steps. The program first builds a representation of the Y-chromosome phylogeny by reading its primary structure from (Newick-formatted) text and then importing phylogenetically informative SNPs from the ISOGG database[1], storing each SNP within a specific node and growing the tree as necessary. It then traverses the tree for each individual, identifying for each the path of derived alleles leading to a haplogroup designation.

To learn more about the algorithm, please see our white paper:

`https://permalinks.23andme.com/pdf/23-13_paternal_haplogroups_yHaplo.pdf`

2 Downloading and running yHaplo

yHaplo is available at the 23andMe code repository for non-commercial use pursuant to the terms of the non-exclusive license agreement included with the software distribution:

`https://github.com/23andMe/yhaplo`

To clone the repository, issue the following command from the directory in which yHaplo is to be stored (henceforth `pathTo/`):

```
git clone git@github.com:23andMe/yhaplo.git
```

Alternatively, users can download yHaplo from the repository web site linked above. To do so, click the "Clone or download" link, and select "Download ZIP." Unzip the file, and move/rename the directory to "`pathTo/yhaplo`."

Add the yHaplo directory to your path by, for example, adding the following line your `.bashrc` or `.bash_profile` file:

```
PATH=pathTo/yhaplo:$PATH
```

To test run the software, issue the following command from any directory, again substituting the full path for "`pathTo`":

```
callHaplogroups.py -i pathTo/yhaplo/data/1000Y.subset.genos.txt
```

The program will first read and process a standard set of input files (**section 3**). Next, it will detect from the genotype file's name extension (`.genos.txt`) that the data to be analyzed are in a simple sample-major text format (**section 4.1.1**). It will read these data and identify the Y-chromosome haplogroup for each individual in the sample.

The software can operate on other common genotype formats (**section 0**) and produce several helpful auxiliary output files (**section 5**). To see the full list of command-line options, some of which are described in this manual, issue the following command:

```
callHaplogroups.py -h
```

The most useful auxiliary output files are elicited with the following options:

```
callHaplogroups.py -i projectName.genos.txt -c -hp -ds -dsd -as -asd
```

To test on a larger dataset, you could download the Y-chromosome genotypes for all 1,244 males from phase 3 of the 1000 Genomes Project[2]:

```
ftp://ftp.1000genomes.ebi.ac.uk/vol1/ftp/release/20130502/supporting/chrY/
  ALL.chrY_10Mbp_mask.glia_freebayes_maxLikGT_siteQC.20130502.60555_biallelic_snps.vcf.gz
```

For clarity, rename this file to `1000Y.all.vcf.gz`, then run yHaplo as above:

```
callHaplogroups.py -i 1000Y.all.vcf.gz
```

3 Input files

3.1 Primary tree structure

This Newick-formatted text file codifies the primary structure of the Y-chromosome tree.

```
input/y.tree.primary.DATE.nwk
```

3.2 Phylogenetically informative SNPs

This table includes details for ~20,000 phylogenetically informative SNPs. The contents were curated by the International Society of Genetic Genealogy (ISOGG) and scraped from their website[1] on the date specified in the filename.

```
input/isogg.DATE.txt
```

3.3 Quality control for phylogenetically informative SNPs

Several files are necessary to correct a number of glitches in the file described above. We encourage users to augment these files in light of any further inconsistencies they may find.

Two files correct physical coordinates and ancestral- and derived-allele designations, respectively. These files have the same format as the post-QC SNPs file described in **section 5.1.1**:

```
input/isogg.correct.coordinate.txt
input/isogg.correct.polarize.txt
```

Three files, also formatted as in **section 5.1.1**, indicate SNPs to drop in light of inconsistencies observed in test data:

```
input/isogg.omit.bad.txt
input/isogg.omit.bad.23andMe.txt
input/isogg.omit.branch.conflict.txt
```

This file lists physical coordinates of multiallelic sites to be excluded:

```
input/isogg.multiallelic.txt
```

This file lists SNPs with known, shared, recurrences not reflected in the ISOGG table. Though the software does not use this file, we provide it for completeness.

```
input/isogg.split.txt
```

3.4 Representative Markers

These two files list the names of markers deemed representative of corresponding haplogroups:

```
input/representative.SNPs.isogg.YEARtree.txt
input/representative.SNPs.additional.txt
```

The first was generated by parsing the ISOGG tree of the given year, and the second is a manually edited supplementary list. yHaplo ignores the first column of each file.

3.5 Sample genotype data

This file bears the Y-chromosome genotypes of 35 globally diverse males at ~60,000 SNPs:

```
data/1000Y.subset.genos.txt
```

These data are derived from full sequences generated by the 1000 Genomes Project[2], and the file format is described in **section 0**.

4 Genotype data

yHaplo can read genotype data in both variant-major and sample-major orientations. Since haplogroups are properties of individuals, it is more memory efficient to use a sample-major format, but the program will run on variant-major data as long as the full data matrix can fit in memory. This should be the case for sample sizes on the order of ten thousand or fewer individuals, but to call haplogroups in samples on the order of hundreds of thousands or millions, it is probably best to transpose or split the data before running.

4.1 Sample-major formats

4.1.1 Genos

To run on sample-major text data, use: `-i projectName.genos.txt`

The expected format is:

Row 0	Physical coordinates (GRCh37)
Column 0	Sample IDs. The first element is ignored.
Cell (i, j)	Genotype for the individual indicated by the i^{th} row of column 0 at the position indicated by the j^{th}, column of row 0. Genotypes are encoded as single characters from the set { A, C, G, T, . }, with "." representing an unobserved value.

4.1.2 Ped/Map

In this common sample-major format, the `.ped` file has six identifier columns and $2m$ allele columns, one pair for each of m markers. The `.map` file has m rows, one for each marker, ordered as in the `.ped` file. For data in plink[3] format (`.bed`, `.bim`, `.fam`), one can export to ped/map format with the following command:

```
plink --bfile projectName --recode --out projectName
```

To then convert the ped/map data to genos format, use the utility script included with yHaplo:

```
convert2genos.py projectName.ped
```

4.1.3 23andMe internal storage

yHaplo can load data directly from 23andMe's internal data storage. The corresponding options will only work within the 23andMe research environment.

To run on all male customers, use: `-a`
To run on a subset of research IDs, use: `-i projectName.resid.txt`

4.2 Variant-major formats

4.2.1 VCF

To run on VCF[4]-formatted data, use: `-i projectName.vcf`
Or, if the VCF is gzipped: `-i projectName.vcf.gz`

4.2.2 23andMe text download

The utility script referred to in **section 4.1.2** can also convert single-sample text files downloaded from 23andMe. Just rename the file to `sampleID.23andMe.txt` and run:

```
convert2genos.py sampleID.23andMe.txt
```

This file can have header lines whose first characters are "#" or "rsid," and its data columns are assumed to be:

1. SNP identifier. The script ignores this column.
2. Chromosome. The script retains only those rows with values of "24" or "Y."
3. Physical coordinate. Reference human assembly build 37 (GRCh37) is assumed.
4. Genotype. The script drops rows with values not in { A, C, G, T, D, I }.

A fifth column bearing a "second allele" is allowed. The script ignores any row for which the value of the fifth column differs from that of the fourth.

5 Haplogroup output files

yHaplo generates a log file and a haplogroup calls file. Users also have the option to generate any of several helpful auxiliary output files. The `-o` option specifies the output directory, which is `output/` by default.

5.1 Haplogroup calls

File name: `output/haplogroups.projectName.txt`

Columns

1. ID
2. Haplogroup short form, with the name of a SNP observed in the derived state
3. Haplogroup short form, with the name of a representative SNP
4. Haplogroup long form, using Y-Chromosome Consortium nomenclature[5]
5. Prior haplogroup call (if imported)
6. Discordance indicator (if prior call imported): "." = concordant, "*" = discordant

Example line

```
HG01791 R-M167 R-M167 R1b1a2a1a2a1b1a1 R1b1a2a1a2a1b1a1 .
```

Important note on the distinction between columns 2 and 3
The SNP names of columns 2 and 3 may differ. yHaplo picks for each branch of the tree a single SNP to represent the equivalence class of SNPs associated with the branch. Column 3 uses this representative SNP, but the individual may not have been genotyped for it. Furthermore, it is actually possible that the individual has been genotyped for the SNP, and an ancestral allele was observed. This can happen when the ISOGG representation of the tree is incomplete, and the set of SNPs associated with a branch is not a true equivalence class. For example, if there are 10 SNPs associated with a given branch, and we observe 5 ancestral alleles and 5 derived alleles, the true haplogroup is one that shares some portion of the given branch before diverging from it, and the representative SNP may have arisen after this divergence. In contrast, the SNP cited in column 2 will necessarily have been observed in the derived state for this individual, although the SNP itself may be less commonly known.

5.2 Counts of ancestral- and derived-allele genotypes

This optional output file records for each individual counts of ancestral- and derived-allele genotypes encountered along each branch visited in the search path. The file contains one block for each individual, with the last line indicating the final haplogroup call.

Command-line option: `-c, --ancDerCounts`

File name: `output/counts.ancDer.projectName.txt`

Columns

Body of each block

1. ID
2. Branch label (haplogroup)
3. Number of ancestral-allele genotypes observed
4. Number of derived-allele genotypes observed

Last line of each block

1. ID
2. YCC haplogroup
3. Prior haplogroup call (if imported)
4. Pipe separator (|)
5. Haplogroup short form, with the name of a SNP observed in the derived state
6. Haplogroup short form, with the name of a representative SNP

Example block

```
NA18960  A0       30   0
NA18960  A1        0  12
NA18960  A1a      15   0
NA18960  A1b       0  30
NA18960  BT        0 333
NA18960  B         1   0
NA18960  CT        0 191
NA18960  DE        0  26
NA18960  E        95   0
NA18960  D         0  36
NA18960  D1b       0   5
NA18960  D1b2     29   0
NA18960  D1b1a     1   0
NA18960  D1b1b     1   0
NA18960  D1b1d     0   1
NA18960  D1b1a2    2   0
NA18960  D1b1d1   29   0
NA18960  D1b1d D1b1d | D-CTS6609 D-CTS6609
```

5.3 Haplogroup paths

This optional output file provides a compact summary of the path through the tree leading to the each individual's haplogroup call. It lists each branch on which derived-allele genotypes were observed and counts thereof. This information is a subset of that described in **section 5.2**.

Command-line option: `-hp, --haplogroupPaths`

File name: `output/paths.projectName.txt`

Columns

1. ID
2. YCC haplogroup

3. Prior haplogroup call (if imported)
4. Pipe separator (|)
5+. Branch labels (haplogroups) and numbers of derived-allele genotypes, colon-separated

Example line

```
NA18960 D1b1d D1b1d | A1:12 A1b:30 BT:333 CT:191 DE:26 D:36 D1b:5 D1b1d:1
```

5.4 Derived-allele genotypes observed

This optional output file includes for each individual a list of SNPs observed in the derived state on the path leading to the individual's lineage. This information is an expanded version of that described in **section 5.3**.

Command-line option: `-ds, --derSNPs`

File name: `output/derived.snps.projectName.txt`

Columns

1. ID
2. YCC haplogroup
3. Haplogroup short form, with the name of a representative SNP
4. Pipe separator (|)
5+. SNPs, each with haplogroup and common name, separated by a colon

Example line (with many SNPs omitted for clarity)

```
NA18960 D1b1d D-CTS6609 | A1:P305 … A1:L1112 A1b:P108 … A1b:Z17900 BT:M42 …

   D1b:M55 D1b:M64.1 D1b:M179 D1b:M359.1 D1b:P37.1 D1b1d:CTS6609
```

5.5 Derived-allele SNP details

This optional output file includes detailed information about each SNP whose derived allele was observed on the path through the tree. Each block is essentially the transpose one row of the file described in **section 5.4**, with additional information for each SNP.

Command-line option: `-dsd, --derSNPsDetail`

File name: `output/derived.snps.detail.projectName.txt`

Columns

First line of each block

As in the haplogroup calls file (**section 5.1**).

Body of each block

1. ID
2. SNP name
3. Branch label (haplogroup)
4. Physical coordinate (GRCh37)
5. Mutation type: ancestral allele and derived allele, separated by a two-character arrow (->)

Example block (with many SNPs omitted for clarity)

```
NA18960 D-CTS6609 D-CTS6609 D1b1d D1b1d .

```

5.6 Ancestral-allele genotypes observed

This optional output file includes for each individual a list of SNPs encountered in the ancestral state during the search. This information is an expanded version of that described in **section 5.5**, and it complements the file described in **section 5.4**.

Command-line option: `-as, --ancSNPs`

File name: `output/ancestral.snps.projectName.txt`

Columns

As in the derived-allele genotypes file (**section 5.4**).

Example line (with many SNPs omitted for clarity)

```
NA18960 D1b1d D-CTS6609 | A0:V148 … A0:L1055 A1a:M31 … A1a:V215 B:M181 E:M40

   D1b1a2:IMS-JST022457 D1b1d1:CTS504 … D1b1d1:Z14880
```

5.7 Ancestral-allele SNP details

This optional output file includes detailed information about each SNP whose ancestral allele was encountered in the search. Each block is essentially the transpose one row of the file described in **section 5.6**, with additional information for each SNP. The file complements the one described in **section 5.5**.

Command-line option: `-asd, --ancSNPsDetail`

File name: `output/ancestral.snps.detail.projectName.txt`

Columns

As in the derived-allele SNP details file (**section 5.5**).

Example block (with many SNPs omitted for clarity)

```
NA18960 D-CTS6609 D-CTS6609 D1b1d D1b1d .

```

6 Additional output files

6.1 Phylogenetically informative SNPs

Upon reading and cleaning the raw set of phylogenetically informative SNPs (**section 3**), the program emits three files.

6.1.1 Post-QC SNPs

This file lists all SNPs considered for haplogroup classification. An individual SNP can have multiple entries—one for each common name associated with it.

File name: `output/isogg.snps.cleaned.DATE.txt`

Columns

1. SNP name
2. Branch label (haplogroup)
3. Physical coordinate (GRCh37)
4. Mutation type: ancestral allele and derived allele, separated by a two-character arrow (->)

6.1.2 Unique post-QC SNPs

This file is similar to the post-QC SNPs file (**section 6.1.1**), but with one entry per SNP.

File name: `output/isogg.snps.unique.DATE.txt`
Format: As in **section 6.1.1**, with a fifth column:
a comma-separated list of all common names for the SNP

6.1.3 Markers dropped from consideration

This file lists all markers dropped from consideration due to inconsistencies observed in test data.

File name: `output/isogg.snps.dropped.DATE.txt`
Format: As in **section 6.1.1**.

6.2 Trees and traversals

6.2.1 Trees

Upon building the tree, the program writes two Newick-formatted files:

```
output/y.tree.DATE.nwk
output/y.tree.aligned.DATE.nwk
```

The first details the topology only, and the second includes artificial branch lengths to align the leaf nodes when plotting. To visualize the final tree in plain text, users can plot it with the provided utility script, which wraps a Biopython[6] function:

```
plotTree.py -n output/y.tree.aligned.DATE.nwk
```

Alternatively, they can plot the tree graphically by importing to third-party tree plotting software.

6.2.2 Traversals

For an even simpler text-based visualization of the tree, use one of the traversal options:

```
-b, --breadthFirst    write bread-first traversal
-d, --depthFirst      write depth-first (pre-order) traversal
```

These yield:

```
y.tree.bf.traversal.DATE.txt
y.tree.df.traversal.DATE.txt
```
